Medical challenges in the management of chemical
crises

The threat by chemical warfare agent came into public focus during the last years. It is obvious that management of chemical warfare agent poisoning is no longer an exclusive military task. Hence, basic medical knowledge on detection, diagnosis, treatment and biomedical verification has to be available. At present, nerve and blistering agents, both have been used in the Syria crisis, are regarded as most important. Basing on relevant scenarios state of the art options for medical management are described and ways ahead on how to close relevant medical gaps are presented.
